TENTH REPORT

TO THE

LEGISLATURE OF MASSACHUSETTS.

RELATING TO THE

Registry and Returns

BIRTHS, MARRIAGES, AND DEATHS,

IN THE

COMMONWEALTH,

FOR THE YEAR ENDING DECEMBER 31, 1851.

BY AMASA WALKER,

SECRETARY OF THE COMMONWEALTH.

BOSTON: WHITE & POTTER, PRINTERS TO THE STATE, 1852.

ADVERTISEMENT.

Commonwealth of Massachusetts.

Secretary's Office, Boston, December 1, 1852.

To the Honorable Senate and House of Representatives:-

I have the honor herewith to transmit, according to law, the Tenth Registration Report of Births, Marriages, and Deaths, it being for the year 1851.

It is the Third Annual Report from this office which has appeared since the Act of 1849, and was made under the superintendence of Josiah Curtis, M. D., of this city.

The returns, with few exceptions, which are alluded to in the *Notes* at the end of the Report, still show increasing fulness and accuracy. The number of Births and Marriages registered and returned during the year was larger than that of any former year. This is true also of the number of Deaths, if we except the single year of 1849, when the cholera prevailed in the Commonwealth.

Ten years of Registration having now passed, the statistics are sufficiently extensive for us to draw very reliable conclusions.

Among other deductions there might be computed a very accurate Life-Table, which for all purposes of life insurance

in the Commonwealth would be the safest of any within our knowledge. Our companies at present base their transactions upon tables constructed from data on the other side of the Atlantic.

The present Report embraces some points of information not given in its predecessors, while other points are carried out somewhat farther than hitherto, as accumulated facts enabled and invited.

The official United States Census of this State, for 1850, will be found inserted in this Report. It is the first time it has ever been published from a copy with the corrections of the Census Office. Being placed by the side of that of 1840, the rate of increase in the various towns will readily be seen. This will be found in the aggregate, for the State, to be 256,814, being a trifle less than thirty-five per cent. on the enumeration of 1840. The increase during the ten years previous, viz.: 1830–40, was only 20.85 per cent.

Of the increase between 1840 and 1850 the Americans numbered 127,184, and the foreigners 129,630. This shows an increase of only 18.09 per cent. among the native population, while the foreign population increased no less than 372.30 per cent., or over twenty times as much as the increase of the native population.

During the three past years, very near the middle of which period the census was taken, the annual average of Births, Marriages, and Deaths, to the population, was respectively one birth in 36, one marriage in 102, and one death in 53. The excess of Births over Deaths during the same period amounted annually to 8,719.

These and other facts, of equal or greater importance to the happiness and well being of the Commonwealth, will be found in the tables of the Report, and alluded to in the observations, which render them worthy of critical perusal, and tend to show the great utility of the Registration Law.

Respectfully submitted, by

AMASA WALKER,

Secretary of the Commonwealth.

SUMMARY OBSERVATIONS.

The year 1851 commences with the last half of the nineteenth century. It forms a very fitting epoch, therefore, from which to glance into the more immediate past, and allow the lessons which it reflects to throw their light upon the future.

Ten years of registration are now already past; and the present report covers the eleventh year. During the first decennial period, ending December 31, 1850, there were recorded in Massachusetts, and returned to this office, the particulars of 163,864 births, 57,952 marriages, and 115,904 deaths, exclusive of stillborn; and the year 1851 adds thereto 28,681 births, 11,966 marriages, and 18,934 deaths, being the largest number of any year in the history of our Commonwealth, with the single exception of deaths in 1849, when the cholera swelled the bills of mortality.

Here, then, we have sufficient data to form a basis for very many highly important deductions, indicating the condition of public health and prosperity in the State, and the general welfare of our citizens, some of the more prominent points of which we we propose to devote a limited time in noticing.

In the year 1789 Dr. Wigglesworth formed certain tables from returns embracing only 4,893 deaths, made to the American Academy of Arts and Sciences, from individuals in the towns scattered along the scacoast from Nantucket to Portland, and from a few interior towns in the counties of Middlesex, Worcester, and Hampshire. These tables were in general use for purposes contemplating the expectation of life, &c., up to the commencement of our system of registration in 1842, and probably to a great extent since, as they were adopted by the Supreme Court in 10th Massachusetts Reports. If the diminutive number of less than five thousand deaths, collected without official responsibility, from a small region of country, was deemed of so much importance, of how much more value will be the results obtained

from the returns from every section of our territory through a period of eleven years, of about one hundred and thirty-five thousand deaths, observed and recorded with more minuteness, and probably more accuracy, and certified to be correct by town officers whose official duties require them to perform the service with as much truthful precision as possible.

The first Registration Report in Massachusetts was made to the General Court in February, 1843, in obedience to the Act of March 3d, 1842. It covers one hundred and twenty pages, and the Hon, John A. Bolles, Secretary of State at that time, expressed his strong approbation of the law, and alluded in decided terms to some of the points of its great usefulness. Among all the town clerks in the Commonwealth whose duty it was to make the returns, but two spoke unfavorably of it. Mr. Bolles states that " of the utility of thorough registration no intelligent person can well entertain a doubt."* He then gives an outline of the systems in operation in England, France, Spain, Austria, &c. &c. Of France he says: "The system of French registration is even more full and perfect than the English, and is, indeed, one of the most admirable specimens of that grand system of laws which owes its origin to the genius of Bonaparte, and which, under the name of the Code Napoleon, will give to his reputation a lustre more enduring than that bestowed by all his military achievements." "This system," adds Mr. Bolles, "is in perfect operation, not only in the 40,000 communes of France, but in Geneva, and in those portions of Prussia and Belgium which came within the jurisdiction of France when the 'Code' went into operation."

The English system was established August 17, 1836, and the first report was made to both Houses of Parliament in May, 1839. The eleventh is now before us, which came from the Registrar General's office, December, 1851.

Massachusetts having followed England with more or less closeness, has in turn been the example of other States.

As observed above, the law in this State was passed in 1842. This law was modified and improved by the Act of March 16, 1844, and still further by the Act of May 2, 1849. The State of

^{*} Page 6. The capitals are his.

New York followed with a registration law, passed April 28, 1847, and made their first report in April, 1848. New Jersey passed a law on the subject March 3, 1848, and remodelled it with improvements by the Act of March 19, 1851. Their report, before us, bears date of February, 1852. The registration law of Connecticut, passed June 24, 1848. We have their three reports; the last is dated May, 1852. New Hampshire passed a less efficient law July 7, 1849, and altered it without much improvement July 4, 1851.

The Act on this subject in Pennsylvania passed the legislature of that State April 14, 1851, and became a law without the signature of the governor, as certified by the proper authorities, January 12, 1852. During the last session of their legislature that body manifested their approbation of it by appropriating \$4,500 to put the law into operation.

On the 9th of January, 1852, the legislature of Kentucky passed a registration law, and the subject will come from influential sources before the next legislature of South Carolina. All of these enactments, and especially the reports that have been made in different States, in compliance with them, bear an analogy to the same from our own State which had preceded them.

This indicates not only the estimated importance of the subject as its results develop themselves, but also the confidence reposed in the system adopted by this State. The former feature, however, has the most notable point.

Population.—The eighth report, for 1848-9, was the first State document which published the seventh U. S. census of Massachusetts for 1850. That was taken from an abstract made by George Adams, Esq., of Boston, one of the assistant marshals for taking the census. It was copied in the ninth report, and has been made the basis of various calculations required by the legislature since.* It will also be found on the new map, which shows the late districting of the State. It is also inserted in the first abstract of this report. It will be found to present some small discrepancies when compared with the official census which is now for the first time published. This latter was furnished by Dr. Josiah Curtis, of Boston, who was indebted for it to the department

^{*} See Senate Documents Nos. 18 and 49, 1852.

at Washington. It is the copy of that which will be officially reported to congress, and will be found in the valuable table (XI.), on pages 54-66, inclusive, and was made the base for determining the ratio of births, marriages, and deaths, to the population in the various counties, cities, and principal towns in the State.

Being placed by the side of the United States census of Massachusetts for 1840, the increase of population during the decade was readily determined, and will be found in the next column of the table last referred to. This shows an increase during the ten years of 256,814, being 34.81 per cent. on the population of 1840. Some sections of the State exhibit a higher proportional rate of increase, and others lower. The county of Middlesex shows the largest proportional increase, it being no less than 51.37 per cent. Next follows the county of Suffolk, whose per cent. of increase is 50.89. These are the only two counties which show a ratio of over fifty per cent. in their increase during the ten years 1840-50. After the two counties above named, follow in order, Norfolk, Essex, and Worcester, whose increase was in each, over thirty-three per cent. Nantucket brings up the rear in the colnmn, and exhibits a decrease of 560, or 6.21 per cent. crease has been mostly confined to the cities and manufacturing villages in those counties which show a high relative augment. as may readily be noticed by reference to those places in the various parts of the table. Taking the principal cities and towns of Boston, Lowell, Roxbury, Springfield, Chicopee, Lawrence, Worcester, Charlestown, Cambridge, the Chelseas, &c., they will be found in the aggregate to have increased over sixty-six per cent.

Upwards of forty towns show a decrease, and a much larger number have remained nearly stationary. Some of the former owe this characteristic to the fact that new towns have been formed, which have embraced a portion of their population. In some cases a new town has been incorporated wholly within the limits of another town, as West Roxbury from Roxbury, Chicopee from Springfield, Clinton from Lancaster, &c.; while in other instances two or three, or more towns have contributed of their territory and population to the organization of a new town. The principles and policy of annexation have also been practised in a few cases; the most notable of which are a portion of Newbury annexed to Newburyport, and a portion of Dracut

annexed to Lowell. These will be more definitely stated, with other minor cases, in the *Notes* appended to this report.

One of the most important elements connected with the increase of population in our State, and worthy of especial consideration, is the high proportional increase of foreigners among us. In our eighth report we alluded to this point, and there gave a table (on page 94,) which was taken from Dr. Chickering's report on the census to the city government of Boston, (City Doc. No. 42, 1850.) This has been transferred to the columns of the American Almanac in a notice of our eighth report. The official returns from the census department at the seat of general government, furnished through the same source that the official census came, show that the statements should receive some modification; corrected it will stand thus:

	18	30.	18	10.	185	50.
Population.	Number.	Per Cent.	Number.	Per Cent.	Number.	Per Cent.
American,	600,788	98.42	702,882	95.28	830,066	83.46
Foreign,	9,620	1.58	34,818	4.72	164,448	16.54
Total,	610,408	100.	737,700	100.	994,414	100.

Thus, it appears, that while there were three foreigners in every two hundred of the population twenty years ago, there were three times the number of foreigners to the same number of natives ten years since, and in 1850 about one out of every six inhabitants in the State were of foreign origin. These are very unequally distributed over the Commonwealth, large numbers of adopted citizens congregating in the cities and larger manufacturing places.

According to the city census of 1850, there were in the metropolis of the State, under five years, 12,143 children of natives and 12,132 children of foreign parentage. Of the births and marriages in Boston during the three years 1849-51, those of foreign origin were nearly two to one over the natives. The same is true also of births in Lowell, Fall River, and perhaps a few other places; and the last of these years shows a much larger

preponderance than the first. In the whole of Suffolk county the proportion of births during the last three years stood thus: of American origin, 34.86 per cent.; of foreign parentage, 61.87 per cent.; not stated, 3.27 per cent.

From the official United States census of 1850, we are able to give the following abstracts, furnished as hitherto stated, which cannot be devoid of interest, as they present many interesting as well as important characteristics of our population.

BIRTHS.

The number of births presented in the returns of 1851, was 28,681, which is a larger number than has been given in any former year. This indicates a degree of prosperity in the State, and furnishes one item correberative of others, which exhibit the prosperity of the inhabitants. During the three years, 1849–51, there was annually one birth to every 36 inhabitants. In Suffolk county, there was one birth in 27. During the five years, 1839–43, there was annually one birth in 31 inhabitants in England; one in 35 in France; one in 26 in Prussia; and one in 26, also, in Austria.**

In the abstracts, it will be noticed that there were less than in former years, among the unspecified as to sex and parentage. It cannot well escape observation, moreover, that the proportion of births from foreign parents is rapidly increasing. Upon this point we have already made some comments. To give the fact more definiteness, we have arranged the number of births during the past three years, distinguishing the number of American and foreign parentage in each county, and casting their proportions as follows:—

	Now we will be the control of the co	Whole Whol	Without With	Number N	Name

By the foregoing abstract it will be observed that nearly thirty per cent. of all the births during the three years, were stated to be of foreign parentage; and of these, the proportion in the year 1851 was still greater. In this particular, as in many others pertaining to the vital statistics of the Commonwealth, Middlesex county seems to be quite a good representative of the whole State. During each of the past three years, the returns from the county of Suffolk have shown quite a majority to be of foreign origin; and during the last two years this preponderance has been nearly in the ratio of two to one. It was 61.87 per cent. in the whole period of three years, against 34.86 per cent. of those having native parents. In this peculiarity, Norfolk county ranks next to Suffolk; then follow in order, Middlesex, Hampden, Bristol, Berkshire, Essex, Worcester, etc. These counties receive this characteristic mostly by the manufacturing towns within their territory. The counties of Barnstable, Dukes and Nantucket, show over 90 per cent. of Americans among the hirths.

Another point worthy of notice is the preponderance of females. A general law seems to govern the proportion between the sexes among those that are born. In all countries, as a general principle, the females appear to be to the males nearly as 106 to 100. Circumstances, however, disturb this relation in different places. In the whole of the births during the five years, 1845–9, the number of births whose sex was stated in the returns, was 92,-272. Of these, 47,228 were males, and 44,214 were females; this gives 107 males to 100 females. During the last three years, 1849–51, there were returned 81,693, of which 42,415 were males, and 39,278 were females, which gives a proportion of 108 males to 100 females.

In England, during the seven years, 1839–45, there were 1,863,892 males, and 1,772,491 females born alive. Of these, therefore, there were 10,515 boys to every 10,000 girls. The proportion, in all England, is nearly 20 boys to 19 girls. The proportion of boys (10,617 to 10,000 girls), is greatest in the northern division, and least (10,455 to 10,000), in the south midland division. Of those only who were illegitimate in the years 1842 and 1845, the boys were only 10,393 to 10,000 girls, which is about 26 to 25. During these years, the proportion of boys to

girls was only 10,510 to 10,000, giving an excess of 117 in 10,000, in the proportion of boys born in wedlock over those born out of wedlock.* During the years 1847–8, of the 564,000 births in England, nearly 140,000 were illegitimate. The proportion of illegitimate births in England, in 1842, was 6.07 per per cent.; in 1845 it was 7 per cent.; and in 1846 it was 6.07 per cent. Of 528,690 married women who had living children in 1846, in England, 5,349, or one in 99, had twins; 27 had triplets, which was one in 19,581. Of 38,230 women who bore children out of wedlock, 293, or one in 131, had twins, and 3, or one in 12,743, had triplets.†

In our own State, the census shows that there are among the living a greater number of females than males. This is accounted for, perhaps, in part, by the fact that a larger proportion of males existed among the emigrants than among the immigrants. However, it admits of doubt; the change is fully accounted for in the tables of mortality, where it is clearly manifest that the preponderance of male deaths under five years of age, is greater than the excess of males among the births.

MARRIAGES.

The number of marriages in the State, during the last year, was 11,966: that embraces 23,932 persons. The number of persons passing this interesting event in life, during the three years last past, was no less than 58,494. The returns exhibit an increasing number from year to year, which is indicative of general prosperity. Our observations have not, as yet, been sufficiently extensive to enable us to draw reliable conclusions upon this point, so definite as to give them mathematical precision. But much more generally than is supposed, do the variations in the number of marriages in any given community, in a series of years, mark the relative prosperity of that people during the same period. In foreign countries this subject has received attention, and the coinciding facts have been stated. Any serious or extended calamity, as war in the country, famine, severe mortality, rise in provisions, or low wages, invariably produces a decrease of marriages, and their opposites, as peace, plenty,

^{*} See English Registrar-General's Eighth Report, pp. 37, 38.

[†]Registrar-General's Ninth Report, pp. 19, 20.

general health; also progression in important scientific discoveries and inventions, has the effect to increase matrimonial alliances. This subject is very ably discussed from extensive observations, covering a great number of years, in the Eighth and Ninth Registration Reports of the Registrar-General of England. In the earlier pages of those reports Major Graham most clearly demonstrates "that it is a fair deduction from the facts, that the marriage returns in England point out periods of prosperity little less distinctly than the funds measure the hopes and fears of the money market. If the one is the barometer of credit, the other is the barometer of prosperity."

In our Eighth Report, page 100, we entered into some calculations to show the proportions of marriages at different periods of life in Massachusetts. In that abstract, it appeared that about one-fourth of the females married during the five years and eight months, from May 1, 1844, to January 1, 1850, were under 20 years of age. This proportion was fifteen times greater with that sex than it was with males under the same age. In England, about eight per cent. of the males married in their minority, and only a little over thirteen per cent. of females. This presents quite a contrast with Massachusetts.

The annual marriages in the last three years, in the Commonwealth, were in the proportion of one to 102 inhabitants. particular, Middlesex county is an index of the whole State. the county of Suffolk, the rate was one marriage in 64. This shows a higher rate than most countries; thus, during the five years, 1839-43, there was in England only an annual average of one marriage in 130; in France and in Austria, one in 123; and in Prussia, one in 110. These countries, however, furnish very much higher statistical numbers than we do, in one particular, namely, those which state the proportion of illegitimate births. It is true, our returns, perhaps, do not designate this last class of facts in all cases; but we think that completeness of record in this respect would not vary the above statement. Nor do the returns with us specify the number of those who sign the marriage certificate with mark, being unable to write, but we apprehend the number, at least of our native population, or of those who have resided in Massachusetts any considerable length of time, is very limited. In England the returns show that a trifle

short of one-third of the males and nearly one-half of the females, sign the certificate with their marks.* This shows that in the rudiments of general education, the masses of our citizens are much in advance of European countries; but in many other respects we seem to be as far in the rear of both England and other enlightened continental nations.

In four of the reports, covering the years 1844–7, an abstract was made with the intention of "illustrating the influence of domestic condition on longevity." To carry out this idea would seem to require facts and statistics of a most extended nature. It would be necessary, among other things, to know the number, the aggregate and average age of each sex of the living who were unmarried, likewise of the married, and also of the widowed, together with the number of each class in the community at the time of making the observations on the deaths from among those several classes; hence the table was omitted in our eighth report, and has been left ever since. In our present report, page 70 will be found the aggregation of all information which had been collected on this point. It was thought best to place it in a permanent form, in taking leave of that peculiar abstract.

The oldest person noticed among the returns of marriages during the year was a male of seventy-two years, who was united to a lady under thirty.

Many young persons have, during the year, united in wedlock, we think a larger number than is usual among persons in their minority: eight females of fourteen, and about forty of fifteen years, have become wives. The ages of males marrying females of fourteen ranged from twenty to thirty-six. The youngest couple were each sixteen only. In Boston one male of nineteen married a female of twenty-eight; and in Worcester county a lad of seventeen married a female invalid who has been unable to stand for a number of years, aged thirty-eight.

Third, fourth, fifth, and sixth marriages are to be found on the records. A male of thirty-six married, for his second time, a female of fourteen; and one of thirty-eight married for his fifth time. In Boston, a negro of fifty-eight was married for his sixth time to a negress of fifty-five, it being her third marriage.

^{*} Registrar-General's Eighth Report, p. 34.

DEATHS.

In order to understand fully the apparent results of the mortuary abstracts in the several reports, it is necessary to keep a few essential points constantly in mind. While in some particulars the returns from the first are reliable, and may enter into our calculations, in other particulars the earlier reports ought not to have weight only as approximations to the truth, and in some other particulars they give no correct evidence of real facts. Because the latter peculiarty exists the former should not of necessity be discarded. For instance, a county may not send returns from more than half of its towns in some given year. returns, so far, might indicate approximately the relative proportion of deaths which each month bore to the whole number for the year; also, the relative proportion of the mortality which each age sustained; but such a partial return would not be a true criterion for estimating the proportion which the deaths bore to the living in the whole county, unless the population of those parts which were unrepresented in the returns was deducted before making the estimate. Because the latter difficulty exists it forms no objection to the validity of the former. Many points of a somewhat analogous nature should likewise be observed where the returns are full and complete. Thus in one year a section, or the whole State even, may be visited by a fatal epedemic, which shall decimate our population, as the plague, smallpox, and cholera, have done in other countries. The mortality of such a year would be no just index of the general annual mortality among us; all this may occur where the returns are perfect. If such epidemic was particularly fatal to the young, and at some particular season, the record and its just abstracts would furnish no true representation of the general law in the case, which is accustomed to distribute the mortality among different ages and seasons of the year, except so far as that single year is concerned.

There is one other point which seems to demand notice. Many persons, little used to investigations of this nature, are accustomed at first, to receive the average age at death, as given for every town in the last three reports, and aggregated in this report, as a correct measure of the relative healthiness of different communities, and they set down the cause of the increased mor-

tality which they suppose indicated by the lower average age at death in one locality, to occupational or some other circumstance.

Now a second thought may show us the proof that the section exhibiting the lowest average age at death may be the most healthy; and indeed, that the characteristic above noted may be only apparent. Take for example the town of Lawrence, which the census of 1850 gives over 8000 inhabitants, and we observe (table XI. page 57) that during the last three years there were 426 deaths returned, whose ages were given, furnishing an average of 17.95. Take also, for contrast, Nantucket, having about the same amount of population. Here, by the same table (p. 61) we find there were in the same period 310 deaths, whose ages were given. These exhibit an average age of 33.33 years.

Before awarding the difference of 15.38 years of additional life to each individual among those dying in Nantucket, solely on account of advantages from location and occupation, we should consider the fact that the average age of the living, from whom death is to select its victims, differs greatly between the two places. The site of the one was almost without an inhabitant half a dozen years ago, whereas the other is one of the oldest settled places in the Commonwealth; a young, but generally vigorous population, has been drawn to the one, while the other contains a higher proportion of those more advanced in years. If, therefore, when all the abstracts of the United States census shall be published, it shall appear that the difference between the averages of the living, in the two places, is greater than that of the average age at death; from this point of observation alone it will cast the balance into the other scale.

Did time permit, it would be no less useful than interesting, to present all of the cardinal points on which the returns for the last ten years furnish reliable data as well as point out those particulars in which they are most defective. Suffice it to say, that the new law of 1849 requires more minuteness of detail in the returns than before, and some of the provisions of that act have been well calculated to bring more complete returns from every part of the State, including localities which previously neglected to comply with the registration enactments in even a partial manner. Among the latter will be noticed the city of Boston. This accounts for the fact that the number of deaths from speci-

fied causes, in the returns of the three years last past, bears to the like number for the previous eight years, the proportion of 4 to 5. The last three years, moreover, embrace the census year and its contiguous years, so that it forms a period, very near the middle of which, the population was enumerated, and hence a most fitting time for just comparisons between the numbers who have passed either of the three principal epochs of human existence, and the number of the inhabitants in the same territory. this in view we have added much to our labors by bringing out the three years' period in table IX., pages 44-50, and table XI. pages 54-66, in the former of which will be found the number of deaths of each sex, from each specified cause during the period, carefully collected, and the per centage which each item separately bore to the whole stated. This we regard as a most important table, and certainly is altogether more full, accurate, and reliable, than anything which has ever before appeared on this subject in the annals of our State. The latter table was a most laborious and important one, also exhibiting as it does in nearly all the towns the population of 1840 and 1850 with the increase, or, where it exists, the decrease of the same during the decennial period, together with the annual average (taking the three years 1849-51 as the basis of calculation) of births, marriages and deaths with the excess of the first over the last of these, and the ratio which each of the three classes bore to the population at the middle of the middle year, 1850, adding to the line for each town the whole number of deaths whose ages were stated in the returns, also the aggregate and average age carefully computed. In computing the average age at death it has hitherto been almost universally the custom to obtain it only by approximation, calculating it by apportioning the numbers between certain ages and assuming therefor a mean average age. But such has not been the case in the table above alluded to, commencing on page 54.

In this case the actual ages in years, months and days, which in the returns for the last three years have been stated in each of 55,775 deaths have all been separately examined and aggregated, and averaged for each town, county, and the whole State. Nothing so extensive and complete as this has proceeded from public or private enterprise on this point, within the limits of our Union. This will furnish the indicator of the standard of public

health in our Commonwealth when the analytical abstracts of the census shall be published by the general government at Washington, to supply the frame work; and this sanitory thermometer will exhibit as much accuracy as those which now read the degrees of heat and cold in the atmosphere. It is not too much to claim for these vital statistics, so far as they go, the same precision and importance which is awarded to the statistical information contained in the reports of the Registrar-General of England. Of the latter it has been justly said that they "are among the most interesting and instructive documents of the day. are to us what, in an inferior degree, the Saxon Chronicles were to the 11th and 12th centuries. They engrave in brief but expressive phrases, the national vicissitudes, prosperities, trials, and calamities. With those faithful and unerring indices, marriages and deaths, the Registrar-General measures the robustness of national vigor, or probes the depth of national suffering. by those ranks of expressive figures, which permit no exaggeration, and are susceptible of no fallacy, he presents to us a true picture of the present condition of our country and nation. political creed conceals the facts or perverts their meaning. No unjust law orders the distortion of half the truth by the concealment of the other half. These reports are indeed something more than current history; they are the judgments of the time upon itself; and untinctured as they are by party spirit, and unswayed by personal considerations, those judgments are as true and faithful as those of future times can be." *

Of our own it has been said by a writer on public health, just previous to the publication of our eighth report (the first under the new law), which presents many decided advancements over its predecessors under the old law, that "the registration of every case of death, with the attending circumstances of age, sex, locality, diseases, etc., is of great importance. These are a portion of the facts by which the sanitary condition of a people is made known; and without which, sanitary science is impossible. An accurate record of births and marriages is equally indispensable. Like the three quantities which the geometer demands for the construction of a triangle, they form the three great facts,

^{*} Brit. and For. Med. Chirur. Review. January, 1850; pp. 216, 217.

without which the sanitary condition of a people cannot be determined. Notwithstanding the registration laws which have existed for some years in Massachusetts, the returns made under them were very deficient. Within the last few years, however, the laws have been revised, and these facts, which are so important to the welfare of the State, are at present recorded almost with the accuracy of the English Registration system."*

It cannot be expected that all of the useful teachings which the abstracts exhibit and suggest, will be here pointed out. We propose, however, to allude to some of them.

During the year 1851 there have been no less than 18,934 This is nearly fifteen per cent, above the number in the year previous. But 1850, following the cholera year as it did, was a year of unusual health. 1851 may perhaps be set down as a fair average of the health and mortality during a series of years. Nine towns neglected to comply with the law by making returns for this report. These embrace a population of 10,223. Taking this amount from the aggregate population of the State, which is 994,-514, and we have left 984,291 represented. From this we perceive that there was one death in 51.98 of the population, or 1.822 per In the year 1849 it stood one death in 47.95 or 2.086 per cent, to the living. The annual average for the three years, without making allowance for the places which have made no returns, is found to be one death in 53 of the inhabitants as enumerated in 1850. Corrected by allowance as above noted, it would probably be not far from one in 52.25, or a reduction of .75. Different parts of the Commonwealth, however, exhibit a very striking difference in the rate of mortality as will be seen by reference to the tables which show the population and deaths in different sections. Thus, Barnstable, Berkshire and Norfolk counties show a rate of less than one in 70, while in the county of Suffolk the deaths were one in 35. In our eighth report for 1848-9 the State was divided into eastern and western sections. In the former the deaths that year were one in 46.92, or 2.131 per cent., while in the latter they were only one in 53.47, or 1.87 per cent. As we descended to contrast cities with country we

^{*} North Am. Rev., July, 1851, pp. 125, 126.

found a much greater difference. These rates, though rather high, would need but little modification to stand for the true representatives of the same facts, covering the three years 1849-51, so far as indicating the relative proportions of the mortality sustained by different localities. Inasmuch therefore as a large proportion of our entire population are dwelling in and near cities and especially in those parts of our territory which is the most densely peopled, it seems highly desirable, not only to be informed of the actual fact, that, as shown by various ranges of statistics, life is of far less value in such localities than in other portions of the Commonwealth, but also to be informed of the causes which contribute to this state of things as well as also, the remedy. It is confidently hoped that when we shall have occasion to allude to this matter again in a future paragraph, some hints and suggestions will be given which will throw light on the point and perhaps present some elements which have long been at work and which are increasingly still at work producing this very un-It should be remembered that, when in our desirable condition. eighth report we endeavored to picture the different shades of light and dark, as elevated vital force or the severe impress of death distinguished different communities under different circumstances, those colors were derived from facts and observations of a single year as to some points, but we find the general statements there made fully sustained by larger experience covering a longer period and greater numbers, and also the principles which they shadow, fully coincident with those exhibited by investigations beyond the confines of the State. The Registrar-General in his Tenth Annual Report says: "In the first Annual Report from this office in 1839, the mortality in 32 districts of London was calculated, and it was shown that in 1837 the mortality increased from 18 in the healthiest districts, to 32 and 39 in the crowded and poor districts; and as wages are better, and the food more substantial in London than the families of agricultural laborers enjoy, the source of high mortality in cities was traced to the insalubrity of the atmosphere, the causes of which The six Reports which followed contained were enumerated. more information on the subject; and in connection with the census, fully established the early opinions of the influence of air, water and locality on health, and the principle that the mortality

has a tendency to increase as the population increases, but that the unhealthy tendency can be counteracted by artificial agencies; in other words, that the mortality of cities in England is high but that it may be immeasurably reduced. All doubt must be dissipated by the present complete series of facts, which embraces all the elements required in statistics to determine the mortality and duration of life."* And again, upon well tested data he assures the public "that the numbers constantly sick in London were 122,000, and the annual attacks of sickness more than 1,220,000, during the seven years 1838-44. The annual attacks of sickness would have been at least 350,000 less, and the number constantly sick would have been 35,000 less, had the health of London been as good even as that of Lewisham, one of the districts within its own limits." "But," he continues, "not to take an extreme view, nor to be too sanguine - and above all to avoid any exaggeration - let us set down the deaths in London and the deaths that would have happened had the mortality not been higher than it was in Lewisham." Here follows a tabular statement showing that the excess was 97,923 deaths which would not have occurred had the whole of London been as healthy as one of its own districts. Thus 38 persons die daily in London by local and removable causes which the Registrar justly observes may be driven away by legislation. "If this generation has not the power to call the dead from their graves, it can close thousands of graves now opening. The poisonous vapor may yet clear away from London, and from all the other towns in the kingdom; - some of the sunshine, pure water, fresh air, and health of the country may be given to the grateful inhabitants of large towns, by the parting voice of the legislature."+

It may be thought foreign to introduce results in England as analogous to Massachusetts. But whatever may be the general opinion, no individual can give much attention to the subject here who would not find the same causes insidiously at work and similar results equally manifest in Boston and our other cities, as those which, like a destroying angel, are afflicting the large towns in the many-citied kingdom.

Causes of Death. — In Table VIII., pages 38-43 will be found the numbers who have died in each of the several counties in the State from different causes, classified into twelve different groups and also under each of these general heads will be found the number who have died from each member of that particular family of diseases. Did our time permit it would be interesting to compare the mortality of the three past years in the several counties. By a cursory glance it will be perceived that the number of deaths from specified causes in every county, was higher in 1851 than in 1850. This is true also of the number of deaths from epidemic, endemic and contagious diseases, with the exception of the counties of Franklin. Hampshire and Suffolk. greatest difference in the two years among deaths of this zymotic class, occurred in Bristol county, where they were twice as numerous in 1851 as they were in 1850. Dysentery contributed very largely to this increase. In 1850 there were only 55 fatal cases of this disease reported, against 219 in 1851.

In Table IX., page 44 et seq. will be found the aggregated classification in the State, with the per cent. cast not only for the year 1851, but for the three years 1849-51, distinguishing the sexes, for this period, and also for the first ten years of registration in Massachusetts. In this latter column the first four months of the period are wanting as the commencement was from May 1, instead of January 1, 1842.

Zymotics. — Next to the year when the epidemic cholera prevailed in our State, the year 1851 presents the highest rate of mortality from zymotic (epidemic, endemic and contagious) diseases. In 1849 this class furnished 38.70 per cent. of the mortality, and in 1850 the per cent. was only 27.13, while that of 1851 was 28.06, that for the three years aggregated being 31.62 per cent. This is a little higher than that of the aggregated ten years, that being 30.42 per cent. In our neighboring State of Connecticut during the three years, (ending July 31, 1851,) the per cent. from this class of fatal diseases, aggregated, was 32.22. In all places whose mortuary tables we have examined, it forms the highest rate of all classes of disease. This ought not to be, inasmuch as it embraces just those maladies which can most easily be prevented by proper preventive measures. At the alphabetical head of the list of zymotic diseases, we find the Cholera.

This is a disease which prevails in a comparatively mild form, more or less every summer. Fortunately, its epidemic invasions are of rare occurrence. The results of this unwelcome visitant in 1832 and 1849 are doubtless fresh in the minds of all. The Reports on this disease from Boards of Health in various parts of this and other countries, all unite in showing that it selects its victims principally from the class of persons, who from their habits and habitations are already ripe for attacks of typhus, dysentery, or any other epidemic which may chance to prevail.

We made a few remarks on this disease in our eighth report which included the year (1849) when it prevailed to such an unusual degree, and we are not about to repeat what will there be found. Much information, however, concerning the laws which seem to govern this epidemic in various localities, has since then fallen under our observation. It has been justly the cause of so much alarm, being perhaps more dreaded by the community at large than any other disease, that it seems to be worthy of a few passing observations here. Perhaps one reason why it gives so much alarm, aside from its rare occurrence is. that so few who are attacked with it recover. Of the 707 who had the epidemic cholera in Boston in 1849, only 96 recovered, while 611 died. This furnished far more dread on the part of the citizens, and comments from the ephemeral journals, than the Dysentery and Typhus fever although these two diseases raged epidemically to an exceedingly greater extent during the several vears immediately preceding 1849. And typhus (including what was termed ship) fever in particular, prevailed principally among the same class of inhabitants, with whom the cholera was so fatal. During 1849 the cholera, both epidemically and sporadically, was the cause of only 1,188 deaths in the State, while the deaths from dysentery during the same year, amounted to 2,455, or more than double the number. In 1850 a comparatively healthy year, the dysentery produced just the same number of deaths that the cholera did in 1849; while in 1851 it caused 1,674 deaths.

It is the province of epidemics generally, to prevail most severely in the warm weather, especially in the late summer and early autumn months. The following statement will indicate the habits of the cholera in this particular in different localities:

)	Mass.	En	gland.	London.	Liverpool.	Paris.

In the above abstract we have taken the statements pertaining to foreign localities from the Report on that epidemic from the English Registrar-General's office. It embraces 300 pages and is the most complete and elaborate report on that subject which ever came from the press in any country. It is not for us to go into the details or present anything like a synopsis of the history of that fearful destroyer of human life; but it may not be out of place to state a few of its leading characteristics with as much brevity as possible.

First, in relation to its relative influence on the sexes. England and Wales it destroyed in 1849 the lives of 26,108 males and 27,185 females. There being more of the latter sex than of the former in the population, the ratio stood thus, among the male population there was one death from cholera to every 331; and among the females one to every 333, so that the males suffered slightly the most. It is also worthy of remark, that in the early part of the epidemic as well as of every fresh outbreak, the males suffered most; but at its height and decline the female mortality was the greatest. Second; although it proved fatal at all ages, yet the middle period of life suffered Third; we find that the mean duration of the disease was, in males 49.44 hours, and in females 50.44 hours. In this particular it changed as life advanced; thus the mean duration of both sexes, at the age of 15-35 was 50.9 hours, and between the ages of 35 and 55 it was only 46.9 hours. Fourth; the epidem-

ics of 1832 and 1849 each commenced about the same season of the year (the beginning of October) and each lasted about the same length of time, (fifteen months,) each had two eruptions, each followed very generally the same tract and pressed heavily upon nearly the same localities. The temperature seemed to exert much influence, and the sources of water supply some. influence of locality was remarkably great, especially when combined with compactness of population. Of the 53,293 deaths. as given in the preceding abstract, 46,592 in an area of 7839 square miles on which four-tenths of the population dwelt, and only 6701 deaths occurred on the arrea of 49.228 square miles on which lived six-tenths of the inhabitants. But, above all other influences affecting the mortality from cholera, elevation seems to rank preëminent. To illustrate this we compose the following statement respecting London from tables on pages 62 and 64 of the Report alluded to.

Elevation of Districts above high water mark. Feet.	Deaths from Cholera	~ · · · · ·	Number of persons to		
	in 10,000 Inhabitants.	Calculated Series.	An Acre.	A House.	
0- 20	102	$\frac{102}{1} = 102$	74	6.8	
20-40	65	$\frac{10^{\circ}2}{2}$ = 51	105	7.6	
40-60	34	$\frac{102}{3} = 34$	184	8.5	
60— 80	27	$\frac{102}{4} = 26$	152	8.8	
80-100	22	$\frac{102}{5} = 20$	44	7.7	
100-120	17	$\frac{102}{6} = 17$	102	9.8	
	-		-	_	
340—360	7	$\frac{102}{10} = 6$	5	7.2	

This particular law pertaining to elevation is no less important than remarkable. It is due to the Registrar-General, or rather we presume to Mr. William Farr, his efficient coadjutor, for first demonstrating it. If heeded it will prove of great practical utility at home as well as abroad. It was perhaps suggested by the fact that almost universally, localities on the rivers were most subject to severe mortality, and as universally perhaps, of two or more places, that farthest down the river was least exempt from fatal attacks.

Next to cholera in the group of zymotics we find Cholera Infantum. The 383 deaths from this cause in Massachusetts during the year 1851 were nearly all under five years of age. They furnished 2.09 per cent. of the mortality of the year. We have already observed that among all the deaths under five years of age, the males sustain a greater proportion than females. It is hence observable that those diseases particularly fatal to those in early life press more heavily on that sex than this. In this particular malady during the three years' period of the table, (IX. page 44,) the ratio of the mortality between boys and girls was as 96 to 87, these being the numbers of each sex from this cause in every 10,000 deaths from all specified causes. We find a similar preponderance of males among those who died of the *Croup*. They stand here 105 males and 88 females in every 10,000 deaths.

Diarrhea appears to be a much less fatal disease in our State than in England. It produced only 81 per cent. of the deaths of 1851, and only 1.09 per cent. of the mortality in the ten years previous; during the years 1849–51 the males were to the females very nearly as 6 to 5.

Dysentery has been extremely fatal in our State when compared with other places, especially in England. It caused 802 in every 10,000 deaths during the ten years 1841-50, and 913 in every 10,000 in 1851. It ranks far above any other disease of the zymotic family. Between May 1, 1848, and December 31, 1850, it produced no less than 9,126 deaths: and this in a population of less than a million of people. In England, with a population (in 1851) of 17,922,768, there were only 3,247 deaths from this disease in 1847, and 2,629 in 1848.* But diarrhea presents a contrast equally striking in our favor. In the three years 1847-9 there were 676 deaths from this last named disease in Massachusetts, against 34,457 deaths in England during the same period from the same cause.* About the same proportion of males and females are given in the returns of England and Massachusetts in both of these diseases, it being slightly the greater against the males.

We have said that these diseases (cholera, diarrhœa, and dysentery) are most fatal during the late summer months. This circumstance has contributed to give currency to the popular idea that they were caused by eating fruits; but there is abundant

^{*} English Registrar-General's Tenth Report, p. 288, and Eleventh Report, p. 294; also, his Report on Cholera, of 1849, pp. 51, 53, and 120.

evidence to show that this is an error. On the other hand the various fruits of our climate are generally quite wholesome, when taken with moderation and temperance, and this remark will apply to persons of ordinary health of all ages.

Erysipelas has somewhat increased. It produced an average of less than a hundred deaths a year during the ten years' period, although during the latter portion of the time it has given an annual average of about 170. This is one of the diseases which have taken most from among females.

Tuphus Fever has been a constant and severe visitant among There has been no year in the history of registration in the State, when the deaths from it have not been above 500. annual average during the ten years has been 576, which gives 565 in every 10,000. In 1851 the number was 773, or 4.22 per cent. of the deaths of that year. It carries from us more males than females; in this particular the ratio stood, for the three years' period, 200 of the former sex to 179 of the latter. It includes those denominated in the returns, ship fever, and bilious fever. Influenza, which not unfrequently prevails as a severe epidemic in England, is but little known as a fatal disease among us. It caused only an aggregate of 381 deaths during the whole eleven years. Measles is a more important disease, but of late has not proved alarmingly fatal in the aggregate. It has caused. however, about twice as many deaths of late years as during the former years of registration. Scarlet Fever, on the other hand, has decreased from 4.37 per cent. during the decennial period, to 2.12 per cent. in 1851. Each of the two last named diseases have been somewhat more fatal among females than males. Smallpox was less fatal in 1851 than during the two previous years. It shows a much higher per cent. since January 1, 1849, than before: partly, no doubt, from the fact that the city of Boston was not represented in the table previous to that date as it has been since, and this fact will also exert an influence on some of the other causes of death.

Diseases of Uncertain Seat. — This class embraces quite a number of diseases, none of which are very severe when compared with the majority of those embraced under the former head, if we except, perhaps, Infantile. This last disease is of course confined to the young, and in accordance with the general law

that at this age the males sustain the higher mortality, we find that they bore a proportion to the females of 1390 to 1049, or in other words, in every 10,000 deaths there were 258 males and 195 females from this disease during the triennial period in table IX., page 45. There were 178 or 33 per cent. deaths from this cause, whose sex was not stated in the same time, which is a larger number than stands opposite any cause of death. Of late, not far from 900 have annually been returned as having died of infantile, a major part of which occurred in the summer months. It will also be found that when we take the population into consideration, nearly four times as many of these were in the cities as in the country districts. This, as almost every other point connected with vital statistics, or with personal observation, contributes to the fact that it is far more difficult to rear a child in the city than in the country. Next to infantile, in this class, ranks Dropsy, which caused 238 deaths in 10,000 of the decennial period. 1851 shows some abatement over the general average during the ten years previous, that giving only 2.12 per cent. Next follow Cancer, which has somewhat diminished of late, and Atrophu, which seems to have increased with equal pace. latter disease is about equally divided between the sexes, while cancer is more severe upon females. The number returned under the general and rather vague term of Debility, have also increased so as to have more than doubled over those of several years back. It is worthy of note that more than three times as many males as females have been reported as having their lives terminated by Malformation.

Nervous Organs.—This class embraces an important series of diseases, and produced 11,413 deaths since 1841. It has been subject to no very great deviations from a regular grade, but has been gradually increasing the number of its victims. During the ten years ending with 1850 it caused 9.28 per cent. of the deaths; during the last three years the per cent. from diseases of the nervous system was 9.93, and in 1851 it was heightened to 10.57 per cent. In the aggregate this class of diseases press more severely upon the male than upon the female sex. It derives this characteristic from no one particular disease, but receives it more largely from Convulsions than from any other individual cause of death; and here is where we should expect to find, in accord-

ance with the general principle that diseases peculiar to the young (and this is an important one of these,) destroy more males than females, as has already been shown. This disease prevailed among the sexes in the proportion of 101 males to 86 females in 10,000.

Respirative Organs. — We here approach the class of diseases which ranks second in fatality. It stands next to, and but little below the Zymotics; and when it is perceived that its fatal cases occur almost entirely from the two diseases, Consumption and Pneumonia, or inflammation of the lungs, it assumes an importance which entitles it to a most serious consideration. Consumption stands far above every other destroyer of human life in It has removed from the citizens of Massachusetts more than ten persons every day during the last three years. exhibits no partiality, unless it be to select its victims from the fairest and most promising. It is confined, however, to no class of persons, no age or season, or locality; united with its congener, pneumonia, they have caused a trifle more than one death to every three from all other causes combined, in the State, during the whole period of registration. The Asiatic cholera visited our State only during a few months of a single year; and yet, in that brief space of time it filled every mind with anxiety and consternation. Its prevalence was principally confined to the lower classes of society, and yet it cost the city of Boston alone. in which there were only 611 deaths, over \$28,000. When has consumption, this much severer and more universal - ever-present life-destroyer, received so much attention? It numbered nearly four thousand victims in the single year of 1851, and over eleven thousand in the last three years. Cholera is supposed to have imparted much of its terror from its very extreme fatality among those attacked; but in this particular it is much below consumption, which is almost universally certain of its victim it once attacks. In Boston, in 1849, six persons died of the cholera out of every seven who had it. Not one in a hundred persons, once afflicted with pure consumption, ever recover.

The office of the lungs is to ventilate the blood. They, and their immediate functional connections, embrace more than one half of the bulk—the machinery and complexity—of our organization. When we consider their delicate structure, and the im-

portance of the position they fill in the purposes of life, it is not strange that fatal disturbances of their healthy action are so liable; and when we observe the general indifference to the elementary but essential principles of health, either from ignorance or wilfulness, instead of appearing strange, it is rather "strange that a harp of a thousand strings should keep in tune so long."

As pulmonary consumption is not confined to densely populated localities, but prevails among the population in country districts as great in proportion, as in cities, so also it is not confined to our State or country, but presents all of its characteristics both among our neighbors and abroad.

In Connecticut, it produced during the three years 1849-51 fully 20 per cent. of all the deaths.* In the State of New Jersey, it produced, in 1851, 832 of the 4023 deaths from specified causes, being over 20 per cent.† In England, the deaths from consumption in the two years 1847-8, amounted to 104,979, which is only a little over 13 per cent.; the whole number of deaths in the same period, from specified causes, being 794,058. In London alone, during the same two years, the whole number of deaths from specified causes was 117,783, of which 13,573, being 11.44 per cent., were from consumption.‡ In Paris during the two years 1849-50, the deaths from consumption were 7829, which, making some allowance for the cholera in 1849, is nearly 14 per cent. of the mortality of those years.§

It is not necessary to multiply facts like these to contrast the relative fatality of consumption at home and abroad. We have become accustomed to the remark that "50,000 persons die annually of consumption in England;" but few are probably aware of the fact, that large as this number sounds, our own bills of mortality, from year to year, show a very much greater proportion of the deaths in our own country to be from this insidious and truly direful disease. We might have given numerous other statements of different localities on this point, but the statements are generally less reliable than those above, all of which were

^{*} Calculated from the returns in the Registration Reports of Connecticut for 1849-50-51.

⁺ Calculated from the returns in the Registration Report of New Jersey for 1851.

[‡] Calculated from the English Registrar-General's Tenth and Eleventh Reports for 1847 and 1848.

[§] Calculated from the Annals d'Hygiene Publique, Tom. XLVIII., July, 1852.

deduced from accurate and reliable statistics, and are deemed sufficient.

We have already spoken of pneumonia. It is an important disease, and causes generally about a quarter as many deaths as consumption. Last year it produced 5 per cent. of all the deaths from known causes in the State, which is a little above the annual average for the past three years.

Diseases of the Circulative Organs comprise but a very small class, and derive their numbers principally from the various affections of the heart. These have very much increased, the ten years' period, giving only 1.91 per cent., while the three years' period gives 2.2 per cent., and 1851 shows 2.46 per cent. No special cause can be assigned for this augment, but it is a noticable fact. Bichat, if we rightly remember, was the individual who compared human existence to a triangle, with the brain—the centre of the nervous system, the lungs—the centre of the respiratory system, and the heart—the centre of the circulative system, for its three angles, out of one of which life generally made its exit.

Digestive Organs. — Diseases of this class, though quite numerous, are nevertheless of much less importance than other classes, if we refer only to those of a sporadic character. In the aggregate they furnish only a little over seven per cent. of the mortality. Teething, and Inflammation of the Bowels, contribute quite largely towards the amount for the whole class. Ulceration, which includes those found in the returns under the term of Canker, is also quite frequently met with. The largest amount from any special head, embraces those under Disease of the Organs, and includes those returned as having died of disease of the stomach, disease of the bowels, &c. Diseases of the Liver furnish only about a half of one per cent. of all the deaths. Hepatic diseases are more frequent as we go south, though not in the proportion that diseases of the lungs diminish.

Class VIII. is principally confined to Child-birth, of which there were 486 deaths during the last three years. That is not far from one to every thousand births in the same time. Deaths reported to have been from Old Age, range at about five per cent. of the total mortality of the State, three-fifths of which were females. As the males predominate among the deaths of those

under five years of age, so the females furnish the largest proportion of those over sixty. A similar characteristic also obtains in other places. In 1848 there were of old age, in England, 11.875 deaths among the males, and 15.645 among the females, while in London alone the proportion of the sexes from this cause during the same year was 748 males against 1423 females. Of those in extreme age, in Massachusetts in 1851, one was a merchant ninety-nine years and three months old, who was born and died in Plymouth; one, of one hundred years and two days, was a farmer, born in Princeton and died in Wendell. The remainder were females, as follows: one, of one hundred years six months and fourteen days, was born and died in Princeton; one, of one hundred and one years eight months and twenty-eight days, was born in Framingham and died in New Salem; one, of one hundred and three years and four months, was born and died in Scituate; one, (colored,) of one hundred and one years and six months, died in Nantucket. These had all been married except one of the females, and perhaps the colored woman, whose condition was not stated on this point.

We have stated that the deaths from old age in Massachusetts, embrace not far from five per cent. In Connecticut, the returns show over seven per cent. attributed to senility, while the returns in New Jersey give only five per cent. to this cause. More accurate returns, however, would doubtless have placed many now under the head of old age, under some other head. The English Reports show a gradual decline of fully one-half; thus, in 1838, they constitute 7.7 per cent., and in 1849 only 3.2 per cent. The source* from which we derive the above statement also informs us that in twenty years in the 17th century (1629–1658) the deaths of London, returned under the head of "aged," were 7.1 per cent., being 15,757 out of 219,250.

Deaths from violent canses comprised somewhat less than four per cent. previous to 1851, when they went up to 4.13 per cent. By far the largest numbers are under the general term of Accidents and under Drowning. The latter are principally found in the returns from the sea-coast towns, and include in most cases those who have been wrecked on our shores, although they never had a residence within the Commonwealth.

^{*} First Report of the Medico Statistical Association, in the Monthly Journal of Medical Science, Edinburgh, Sept., 1852.

The returns do not state, as they should, what number of persons who were drowned in different parts of the State, committed suicide, nor do they state, in cases of suicide generally, what means of self-destruction were used. Different modes for accomplishing this appear to be selected in different countries. In Paris, of the 303 suicides in 1849, there were by drowning 101, and by carbonic acid gas 59, while in 1850 there were 102 by the former mode and 159 by the gas. This latter method, which has become quite popular in France, is not practised much among us. Of the suicides in Massachusetts during the three years 1849–51, there were 24 males to 48 females, and in Paris during the two years 1849–50, there were 497 males to 197 females.*

Occupations. — In our Eighth Report we made a few remarks on this subject. It is a point of much practical importance on which facts are accumulating from year to year. These will soon cover numbers sufficiently large to deduce very truthful conclusions. Already are the numbers of some of the principal occupations extensive enough to warrant much reliance upon the facts which they exhibit, as shown in Table X., pages 50-53. that abstract it will be perceived that agriculturists stand the most favorable on the list, the average age of these being no less than sixty-four per cent. This is fully twelve years above the general average and nearly nineteen years above the average age of those returned as laborers; and eighteen per cent. above that But when we take into consideration that none of mechanics. are embraced in this table who died prior to their 21st year, the difference is in reality much more important.

Had we time to compare those under the general term of mechanics, who are subject nevertheless to different occupational influences, we should arrive at some highly practical and important truths, which, if the lessons they teach should be heeded, might contribute to life and health. *Blacksmiths, carpenters* and *shoemakers* are the three trades which are represented in the abstract by the largest numbers. The last of these, numbers no less than 1274 in the period ending with the year 1850, and

^{*} Annals d'Hygiene Publique, July, 1852.

266 in 1851. Their average age in the former period was 43.31 years, and in 1851 it was 42.22 years. Starting at the commencement of the 21st year of life, then, and these useful artizans have on an average the prospect of living only about 23 years, while the farmer has the prospect of 44 years before him. This is a difference of nearly one-half. Now, according to the census of 1850, (p. 78) there are 55,082 farmers in the State, and 31,944 shoemakers. Next to agriculture there are probably more of our citizens engaged in shoemaking than in any other one occupation. The carpenters number only one-half as high as the shoemakers. The following table will show the number of this latter class of persons in some of the towns largely engaged in the shoe manufactory.

	ition in 50.	of dwel-	of fam-		oemakers.		Number of pairs made annually.	Remarks.	
Towns.	Pepulation 1850.	Number of lings.	Number of ilies.	Number	Males.	Fem'ls.	Number made ar	Nemarks.	
Abington,	5269	833	1070	45	1579	1011	1,658,000	Mostly boots.	
Brimfield,	1420	264	269	19	23			Incomplete.	
Danvers,	8109	1111	1554	35	1184	693	1,124,000		
E. Bridgewater,	2545		538	7	256			Pegged work.	
Grafton,	3904	876	1039	11	418			Mostly pegged.	
Lynn,	14257	1948	3800	114	3787	6422	4,633,900	Sewed work.	
Natick,	2744	552	754	25	859	624	1,113,000	Pegged work.	
N. Brookfield,	1939	288	401	4	423	209	558,000	Pegged work entirely.	
Stoneham,	2085	399	415	24	415	376		Children's mixed.	
Worcester,	17049	2341	3150	18	1144	366	_	Pegged work mostly.	

The number of families in each of the above towns is greater than the number of dwellings, and in one case, Lynn, it is nearly two of the former to one of the latter. In Stoneham the number of males engaged in shoemaking was stated to be just equal to the number of families in the town. In Grafton, a single manufacturer uses one hundred bushels of shoe-pegs a year.

Had we other essential items of information from these ten towns, we might present some highly useful deductions pertaining to the influence of this branch of industry on health and longevity. This can be done, perhaps, when the statistics of the United States census shall be published in full. As in England, Worcester manufactures gloves principally, Leicester stockings, Nottingham lace, Coventry ribbons, Kidderminster carpets,

Sheffield cutlery, Northampton shoes; so in New England, particular towns are largely engaged in special mechanical arts. Lynn is to Massachusetts, in a measure, what Northampton is to England. It has long been said that "you may know when you are within a mile of Northampton by the noise of the lapstones." We have alluded to this town in particular because it is the only place within the scope of our knowledge where the kind of statistics which we want have been obtained. The statistics of All Saints, one of the registration sub-districts of Northampton, is found to be as follows:—

		SEVEN YEA	rs. 1838—	-1844.	
Ages.	tality per cent. of Shoe-	Total annual mortality per cent. in All Saints' Par- ish only.	Total annual mortality per cent. in other parishes of the sub-district.	Excess of mortality in All Saints' Parish.	Excess of mor tality among the Shoemakers, above the gene- ral per cent.
10-20		.515	.474	.041	.403
20-40		.849	.820	.029	.325
4060	1.317	1.606	1.229	.377	100
60 - 80	6.122	6.257	5.893	.364	.047

In the comments of the Report* from which we extract the above, we learn that at the age of 20-60, the shoemakers constitute about one-ninth part of the whole population, which, however, includes their wives and children. The mortality among the shoemakers up to the age of 40 is considerably higher than in the rest of the population of corresponding ages. Of the deaths of shoemakers, nearly one-half were of consumption, and not far from one-eighth, of disease of the heart, two maladies peculiarly severe upon this class of persons everywhere.

Life Insurance. — William Farr, Esq., in a letter to the Registrar-General of England, to be found in his Eighth Report, says:—

"The facts collected under the Registration Act, throw light on the causes that affect the health of the people, and will ultimately lead to the diminution of sickness and the extension of life. This is, perhaps, their most important use. Next to it in interest is their application to the purposes of Life Insurance;

^{*} English Registrar-General's Eighth Report, p. 322.

one of the most valuable discoveries of modern times, and one of the highest branches of commerce, which may be said to have originated in England, and has flourished to the same extent in no other country." Various tables, some quite correct and others very false, have been erected and adopted by the English insurance companies. American insurance companies have adopted the rates of the English companies, as deduced from the tables, showing the expectation of life, or after-lifetime, as it is more properly termed. We have not time here to enter into a calculation from our own State statistics but will give a synoptical view of several of the more important English rates, as follows:

Annual Life Premiums to insure £100, or \$100. English Table. Equitable No thampton Northampton Carlisle Table, by Dr. Price. Table. Experience Table. true Age. Table. Males. Females. (Milne.) 1.549 2.179 1.597 1.555 1.494 1.517 20 2.667 30 2.054 1.963 1.952 1.967 2.067 2.731 2.575 2.599 2.687 2.869 3.398 40 3.873 3.992 4.202 4.530 50 3.627 3.622 6.366 6.1295.734 5.790 6.3026.93560

It has been proved that Dr. Price's Northampton table is incorrect; and it will be perceived above that during the ages when the greatest number of life insurances are effected, that the premiums demanded are much too high; and yet it is used by some companies abroad and perhaps in America.

The only life insurance company in this country whose calculations from its own experience have fallen under our notice, is the "Mutual Life Insurance Company of New York." The actuary of that company, in his report to the board of trustees in February, 1851, states, from data of much reliance, carried through an experience of eight years, that in the northern United States the probabilities of living are less than in England. He has constructed a table in which he makes a comparison between the mortality per cent. of all those residing north of the southern line of Virginia and Kentneky who have been assured in that company during the eight years, and the same of all those whose lives have been assured by fifteen English companies of the longest experience. The greatest difference exists among those over 65 years of age, where the per cent. of mortality was in

America 8.98, and in England 5.18. In both countries, however, the mortality takes a startling stride after the age of 55 years, above that of those who are under that age. The general results are "not such," says the actuary, "as to authorize us to conclude that the force of vitality in this portion of the United States, is as great as it is in England."

This fact we believe is generally understood by those interested in life assurance among us, who of course govern themselves accordingly, or suffer accordingly; or, as Mr. Gill, the actuary above quoted states it: "These results present as yet, no reasonable cause of alarm to those companies whose rates of assurance allow, as the rates of all companies should do, a sufficiently large margin beyond the rates actually deduced from the English tables of mortality. To those companies, however, which, on the unwarrantable supposition that human life is better on this side of the Atlantic than it is in Europe, have made their rates equal to, and in some cases less than those actually resulting from the [foreign] tables, these results are a sufficient indication that unless they change their rates, they must be ultimately unable to fulfil their contracts."

Mr. Gill, the intelligent actuary of the company, from whose report we make the above remarks, says: "It is a well known result of all the European contributions to vital statistics, that a marked change, the causes of which are but very imperfectly understood, takes place in the law of mortality about the age of 55; so much so that Mr. Farr, in constructing the 'English Life Table' for the Registrar-General, actually used different mathematical laws for the formation of his table before and after this age, and this period has been called the 'break of life.'" He terminates his report with the following counsel: "These considerations induce me to recommend the trustees to confine their assurance business, so far as the issuing of new policies is concerned, to lives below the age of 56."

In reverting to the general subject of the mortality of the State, we at once observe many points well calculated to arrest the attention of every true philanthropist and real statesman. The tables show in rugged and unmistakable outlines that large numbers of valuable lives are sacrificed annually in the State, which, with proper sanatory improvements, that could readily be named,

might have been saved. In addition to this actual waste of life, there is much avoidable sickness and general enervation of physical energy, the amount of which it is hard to estimate. A few years ago it was estimated by the celebrated Dr. Warren, of Boston, that the temperance cause had augmented the physieal power of the State one-sixth.* If a reformatory change in the habits of the people pertaining to a single article as a beverage had wrought, or was capable of effecting (and no true physiologist will hesitate to admit it) such a valuable result, what arithmetic can calculate the advantages upon the public, especially in our cities and more densely peopled villages of a complete system of health measures, such as it is within the province of legislators to require, and in the power of the people to adopt. Such, however, cannot be expected until the public are made acquainted with the lessons which our system of registration is teaching, by having them presented in plain and comprehensive language. Not these alone, but our English neighbors, who were our pioneers in laws and investigations upon the subject of public health, are furnishing annually a mass of information on the subject, corroborative of, or, rather, they are so extensive and systematic as to demonstrate with almost mathematical precision the truths which our reports shadow forth.

When the facts on this subject become generally known among our citizens, as they have been presented in countries abroad—England, France, Germany, Sweden, Prussia, &c. &c., they cannot fail to awaken public sentiment and enlist a universal interest here, as it has in other places.† The Public Health Act of the British Parliament, establishing a General Board of Health, will form as fitting a precursor of a like measure in our Commonwealth as the English Registration Act from the same source did of our Registration Act ten years ago, which in turn has been the precursor of like enactments in at least half-a-dozen

^{*} Warren on Health, 2nd edition, 1845.

[†] Dr. Guy, of King's College, London, &c., says: "I do not fear the charge of exaggeration, when I claim for the sanitary question the right to be regarded THE great question of the day. Look at it as a question of humanity, and it will not suffer by comparison with the highest efforts of the philanthropist; regard it as a great act of justice, and here, too, you will acknowledge it prefers peculiar claims to consideration; measure it by the rule of economy, and I hesitate not to affirm that it stands without a rival; or view it in its moral relations and reactions, and I know not whether even the great question of education will take rank before it."

other States of our Union already. The English Health of Towns Bill, introduced by Lord Morpeth, (now Earl of Carlisle,) and so ably supported by him and others in Parliament has been the cause of presenting an array of facts to the people which are most convincing in their show of healthful results from the adoption of disease-preventing measures. It has not only given a more tangible form, and a more practical application, to the principles presented by the Registrar-General in his Reports, but its working has developed and disseminated among the citizens interested, the most convincing proof that the whole truth had not been told.

In the debates* on the bill above noticed Lord Morpeth stated, from Dr. Guy, of King's College Hospital, that the mortality in England was—

			In C	ountry	District	s. To	wn+ Distric	ets
Population to square i	nil	e, -	-	1	99		5,100	
Annual deaths in 10,0	000	, -	-	1	193		271	
" excess in town	ıs,†		-	-	-	78		
Rate of mortality,			-	1 in	52		1 in 37	
The rate of mortality	in	England	was	-	-	1 in	45	
Isle of Wight,		-	-	-	-	"	5 S	
London,	-	-	_	-	-	"	39	
Leeds and Birn	nir	gham,	-	-	-	"	37	
Sheffield,	_	-	-	_	_	"	33	
Bristol, -	-	-	-	-	-	"	32	
Manchester,	-	-	-	-	-	"	30	
Liverpool,	_	-	-	-	-	"	29	

By this it appears that the excess of mortality in the large towns is more than 40 per cent. above that of the country districts, and, that of the inhabitants of London, compared with England at large, lose eight years of their lives, while those of Liverpool lose nineteen. Another view of the matter indicates like results: the average age at death in Lancashire (the county containing Liverpool, Manchester, &c.) was twenty-two years,

^{*} Hansard's Parliamentary Debates, Vol. XC., third series, page 619.

[†] The English designate as Towns such places as are known as cities among us.

and in Liverpool alone, only seventeen, while in Wi!tshire it was thirty-five.

But, as before intimated, our own statistics coincide with those of other countries; thus, in the report of 1849, we find that there was—

Was					
		Pop'n	to sq. mile.	Deaths, per ct	., or one in
In five western counties,	-	-	65	1.87	53.47
In nine eastern counties,	-	-	191	2.13	46.92
		Av	erage Age.		
Country districts, -	-	-	31 yrs	. 1.70	58.69
Cities,	-	-	21 "	2.83	35.30
Boston alone,	-	-	20.5	3.70	26.99
		No. of I	nhabitants.

Back Bay, "	-	-	5121	1.09	52.07
Broad, Cove, and Sea sts.,	, (Bo	oston,)	2813	5.65	17.06

It is necessary to observe that the above statistics of localities in our own State, are not on so extensive a scale as those of European structure, but the story they tell, so far as they do go, is of a piece with that from the Euglish tables. Those showing the western and eastern division of the State, also those embracing cities and country, were from the Eiglith Registration Report for the year 1849. That for Boston alone is from tables of the present report, embracing three years—'49-51; and those showing three districts in Boston were from observations in 1850, by a writer in the North American Review.*

We will define these three districts from the writer's own comments: "The first section which we have selected comprises the portion of Boston between Beacon and Pinckney Streets, inclusive, extending from the State House to Charles Street. Belknap and West Cedar Streets were not included. This section of the city is all high land, and thoroughly drained by nature. The houses are large and well ventilated. The population in this district is 2615, of whom 2054 are Americans and 561 foreigners. The latter are probably mostly domestics in the families of the former.

[&]quot;The next section is upon the 'Back Bay.' It contains the

^{*} North Am. Rev. No. CLII., July, 1851, pp. 121-2.

district which is included between Pleasant Street and the Marsh, and extends from Providence Railroad to West Orange Street. It is composed entirely of new-made land. The streets are narrow, the sewerage and drainage are imperfect. The houses are small, and built around alleys, as well as upon streets. The population is 5121, of whom 1348 are Americans and 3773 are foreigners. The native population are mostly trades-people and mechanics. They are intelligent, and are as attentive to the known laws of hygiene as the average in any community.

"The last district selected for comparison comprises Broad. Cove, and Sea Streets. These streets are situated near the They are built principally upon made land, and have numerous blind alleys leading from them. The streets and alleys are badly drained, and crowded with an overflowing population. A large number of the houses have no means of sewerage whatever, and all their refuse of every description stagnates about the yards, spreading on every side poisonous exhalations, laden with disease and death. A majority of the houses contain several families, and some of them have no less than nine or ten. Even the cellars of the houses are often inhabited, and in some instances one cellar leads to another, and this to a third, a sort of dungeon, all inhabited by human beings of both sexes and every age. The population of these three streets is 2813, of whom 2738 are foreigners and only 75 Americans. The mortality was one in 17.6 of the population, or 5.65 per cent., and this was a year (1850) remarkable for its healthiness. What it would have been in a sickly year we dare not conjecture.

"We were at first inclined to regard these figures as an exaggeration," adds the above writer. "We could not believe that a portion of Boston is annually almost decimated of its population. But a careful reëxamination has confirmed the accuracy of the statement."

Thus we find that facts and observations recorded and noticed, whether in Europe or America, are contributing to the same great end by teaching the philanthropist and statesman where the evils lurk, by removing which the human race can be elevated, life prolonged, and health preserved. And why not? The principles of life and health form an important chapter in the code of nature's laws, and are therefore of universal application. Obs-

dience gives life and happiness, and disobedience is inevitably attended with the reverse, as well in old England as in New England; and this holds true with the individual—the unit, and with communities—the multiple. Similar results are forced upon us, whether our investigations lead us to compare country with town abroad, or country and city at home,—whether we contrast section of country with section of country, or section of city with section of city, either in transatlantic or cisatlantic regions.

We have descended thus to particulars respecting specified sections because they present strong contrasts, and hence are the facts that are first noticed and that first make an impression on the inquiring mind. That portion of our citizens inhabiting the salubrious hills of Berkshire, or dwelling in the beautiful valley of the Connecticut, with all of the insignia of health ever fresh before their eyes, cannot realize the actual state of things which exists in every considerable city in our State. Many and many a hole, in our densely populated towns, is inhabited by a horde of human beings who pay a fat per centage on the value of their dens by way of rent, which almost any farmer in the country towns, should he see his swine in such a squalid situation, would not rest until he had apologized to them by bettering their condition.

We read and hear much about impoverished and famished Ireland; and some have contributed to relief because they entertain the idea that the failure of the potato crop brought famine on that country, and others have done the same who thought that the failure of the potato crop was not the prime cause of famine, but rather the fact that Ireland had allowed itself to depend on the success of the potato crop with the penalty of a famine. Much, too, comes to our eyes and ears, and our hearts, descriptive of the thousands who are reaping the fruits of merciless physical circumstances in the cities of the old world, when similar-conditioned specimens of human degradation, not far removed from our own thresholds, are unknown in effect if not in fact. Our commiseration is alert when we read that "Three wet days will bring the greater part of thirty thousand street people in London to the brink of starvation,"* or when we are made

^{*} London Labor and London Poor.

acquainted with the volumes that come to us teeming with pictures of agglomerated vice and filth, spiritual and physical depravity, with a finis of epidemic death; or even when they paint in lighter shades the demoralizing influences of these polluted dwellings on a new comer, unaccustomed to them.

Such outlines make the whole heart sick and force us to

hope and believe they are confined to foreign soil. But every "minister at large" or city missionary and dispensary physician in Boston, Lowell, &c., would be liable to mistake these, were the names of foreign localities omitted, for unexaggerated descriptions of places-Fort Hill, or The Acre-in our own cities. An able writer already referred to, and who sustains neither of the above-mentioned positions, says: "We are told a great deal of the contrasts of European life. We have heard much of famine in the midst of plenty; of splendor set off by squalid misery; of abject wretchedness showing its guant and deformed features by the side of ease and luxury. Undoubtedly this is true. We can bear personal testimony to the accuracy of the picture. And yet we can recall, neither from our own observation nor from the statements of others, any contrasts of life (not even in London) greater or more striking than observed in Boston, and which may be gathered from the columns of the City Registrar's account of the mortality of Boston. * beings, men, women and children, boys and girls, herding together like swine, and like swine wallowing in filth, and worse than swine steeped in vices that we dare not mention, may be seen by any one who will visit Burgess Alley and other localities in the Broad Street district." A few descriptions of places in our midst have already been given to the public.* We have been told of a single Ward (VIII.) in our metropolis, which, according to the census of 1850, embracing an aggregate of only 480 inhabited dwellings, contained over 200 dwellings with an average of seven FAMILIES to each house. †

[†] Census Report: City Doc. No. 42, 1850. Calculated from Table D. p. 32.

We stop not to extend the catalogue here. We may have appeared too specific already, but no especial pains has been taken to avoid some detail of prominent points. We think that these cardinal features should be clearly presented to the minds of those who have it in their power to institute remedies for such social, moral and vital evils. The judgment of our citizens is not altogether dormant, when statements are made showing the dregs of social and physical life in Leeds, Liverpool and London. They should know that the worst places in those cities are not without their counterpart and parallel within the borders of our own Commonwealth, and fully as extensive too, if the difference in age and population of the localities are taken into account.

But abroad they have already entered manfully on the work of reform. Amid all of its political changes France is incessantly contributing of her treasure and talent, to elevate the physical condition of her citizens. With the directing and protecting hand of Parliament, England is daily improving the condition of her citizens. Measures are quite advanced, in many localities, which elevate and save life. Model lodging-houses have had the effect which was anticipated. They have reduced the mortality more than one-half among the population occupying them, and utterly exterminated typhus fever from their occupants. Says a foreign writer, "It has been proved in the Report of the General Board of Health, that every efficient sanitary improvement, has been followed, as directly as cause and effect, by a corresponding decrease of sickness and mortality. There is no exception to this rule."

When our own people learn this from practical legislation, as England has done, some thousands of lives, on a moderate calculation, will be saved annually, in the cities of the Commonwealth, the physical power of the State will be elevated, and the health, happiness, moral dignity, and intellectual greatness of our citizens will be equally augmented.

NOTES.

THE abstracts in reports which have preceded this have been accompanied by more or less copious notes, which were deemed essential to their full appreciation. These generally related to the imperfections, or other modifying circumstances, connected with the returns. By recurrence to some of the earlier reports, these explanatory remarks will be found to be quite lengthy, and to consist chiefly in extracts from the letters with which the town clerks accompanied their returns. As the law is now better understood, and its practical workings have become more familiar, greater accuracy and completeness, with less comment, have characterized the returns from the various cities and towns of the Commonwealth. Although the fact has been already repeated, yet it is still worthy of additional notice, that the returns of each year are marked by perceptible improvement over their predecessors in general and special fulness, as well as undoubted accuracy. Still, it is not to be expected that perfection will exist in the returns of over 25,000 births, over 10,000 marriages, and near 20,000 deaths, occurring annually, among a million of people, all required to be recorded with much minuteness of detail. and returned to this office, from the hands of some three hundred and twenty-five different civil State officers.

Towns Making no Returns.—With all that has been said, without any action, a few towns are uniform in neglecting to make returns. The oaths of office have been violated in this matter by the town clerks of Dennis, in Barnstable County, who has made no returns of either births, marriages, or deaths, since 1844; and of Upton, in Worcester County, from whom nothing on this subject has been heard since 1845. With the exception of returns of marriages in 1850 and 1851, the clerk of the town of Cheshire, in Berkshire County, and except returns of births and deaths in 1850 the town clerk of Rowe, in Franklin County, should both be placed in the same cataloguege with those of Dennis and Upton.

In addition to the above the following towns are noted for neglecting to make returns for this report, viz.: in Berkshire County, Clarksburg and Savoy. New Ashford also neglected to make returns of deaths. In Franklin County, Conway made no returns of births. In Hampshire County, Enfield made no returns, and Greenwich none of births.

According to the returns there were no marriages in the town of ${\it Hull}$ during the year.

Some of the other towns have been more or less remiss in various particulars, among which should be most prominently noted the city of Salem, the clerk of which seems to be almost entirely regardless of that part of the law which pertains to the items of the marriage returns.

The town of *Malden*, in Middlesex County, is almost the only town in the State which sends returns to this office one year behind-hand.

In the returns of births during the last three years, from the town of *Lancaster*, in Worcester County, there are mingled the records of many former years, going as far back as thirty and forty years ago.

The causes of death have been quite indefinitely stated in some instances.

One is returned as having died of disease of the heart, being only one day old. This was doubtless a case of imperfect development, technically termed *Cyanosis*. One farmer in Worcester County, of eighty-seven years, was returned as having died of "old man's foot," and one female in the same county, of fifty-nine years, was reported as having been "poisoned by corn plaster;" while another person still is said to have died of "congress water and warm baths." A few cases are reported where the fatal malady is stated to be a "chronic complaint."

The following changes in the limits of town boundaries have taken place during the year by acts of the Legislature of 1851:—

BERKSHIRE COUNTY. — By the act of May 24, chapt. 265, a small amount of territory, inhabited by about seventy-five persons, was set off from the town of New Martborough and annexed to Monterey.

ESSEX COUNTY. — By the act of April 17, chapt. 54, a tract occupied by 2880 inhabitants, was set off from the town of Newbury and annexed to Newburyport. This act reduces the population of Newbury to 1546, and increases that of Newburyport to 12,452.

MIDDLESEX COUNTY. — By the act of February 28, chapt. 8, a part of the town of *Dracut*, having an estimated population of 1800, (the number of voters was 266,) was set off therefrom and annexed to the city of *Lowell*.

NORFOLK COUNTY. — By the act of May 24, chapt. 250, the new town of *West Roxbury* was incorporated, with about 3500 inhabitants, all of which was taken from the city of *Roxbury*.

Worcester County.—By the act of May 24, chapt 293, a small area, occupied by not far from fifteen persons, was set off from the town of Rulland and annexed to Paxton. By the act of May 24, chapt 293, certain farms, also consisting of about ninety acres, but represented to be "without the very first inhabitant thereon," were set off from the town of Winchendon and annexed to Gardner.
